The work presented has been carried out by:

- Rodolfo Repetto DICAT, University of Genoa, Italy;
- Jennifer Siggers Imperial College London, UK;
- Alessandro Stocchino DICAT, University of Genoa, Italy;
- Julia Meskauskas DISAT, University of L’Aquila, Italy;
- Andrea Bonfiglio DICAT, University of Genoa, Italy.
Anatomy of the eye
Vitreous characteristics and functions

Vitreous composition

The main constituents are
- Water (99%);
- hyaluronic acid (HA);
- collagen fibrils.

Its structure consists of long, thick, non-branching collagen fibrils suspended in hyaluronic acid.

Normal vitreous characteristics

- The healthy vitreous in youth is a gel-like material with visco-elastic mechanical properties, which have been measured by several authors (???).
- In the outermost part of the vitreous, named vitreous cortex, the concentration of collagen fibrils and HA is higher.
- The vitreous cortex is in contact with the Internal Limiting Membrane (ILM) of the retina.

Physiological roles of the vitreous

- Support function for the retina and filling-up function for the vitreous body cavity;
- diffusion barrier between the anterior and posterior segment of the eye;
- establishment of an unhindered path of light.
Introduction

Vitreous ageing

With advancing age the vitreous typically undergoes significant changes in structure.

- Disintegration of the gel structure which leads to vitreous liquefaction (synchisys). This leads to an approximately linear increase in the volume of liquid vitreous with time. Liquefaction can be as much extended as to interest the whole vitreous chamber.

- Shrinking of the vitreous gel (syneresis) leading to the detachment of the gel vitreous from the retina in certain regions of the vitreous chamber. This process typically occurs in the posterior segment of the eye and is called posterior vitreous detachment (PVD). It is a pathophysiologic condition of the vitreous.

Vitreous replacement

After surgery (vitrectomy) the vitreous may be completely replaced with tamponade fluids:

- silicon oils water;
- aqueous humour;
- perfluoropropane gas;
- ...
Partial vitreous liquefaction
Motivations of the work

Why research on vitreous motion?

- Possible connections between the mechanism of retinal detachment and
  - the shear stress on the retina;
  - flow characteristics.

- Especially in the case of liquefied vitreous eye rotations may produce effective fluid mixing. In this case advection may be more important than diffusion for mass transport within the vitreous chamber.
  Understanding diffusion/dispersion processes in the vitreous chamber is important to predict the behaviour of drugs directly injected into the vitreous.
**Retinal detachment**

**Posterior vitreous detachment (PVD) and vitreous degeneration:**
- more common in myopic eyes;
- preceded by changes in vitreous macromolecular structure and in vitreoretinal interface → possibly mechanical reasons.

- If the retina detaches from the underlying layers → loss of vision;
- **Rhegmatogeneous retinal detachment:** fluid enters through a retinal break into the subretinal space and peels off the retina.
- **Risk factors:**
  - myopia;
  - posterior vitreous detachment (PVD);
  - lattice degeneration;
  - ...

Scleral buckling and vitrectomy

**Scleral buckling**

Scleral buckling is the application of a rubber band around the eyeball at the site of a retinal tear in order to promote reattachment of the retina.

**Vitrectomy**

The vitreous may be completely replaced with tamponade fluids: silicon oils, water, gas, ...
Intravitreal drug delivery

It is difficult to transport drugs to the retina from 'the outside' due to the tight blood-retinal barrier → use of intravitreal drug injections.
The effect of viscosity

Main working assumptions

- **Newtonian fluid**
  The assumption of purely viscous fluid applies to the cases of
  - vitreous liquefaction;
  - substitution of the vitreous with viscous tamponade fluids.

- **Sinusoidal eye rotations**
  Using dimensional analysis it can be shown that the problem is governed by the following two dimensionless parameters

\[ \alpha = \sqrt{\frac{R_0^2\omega_0}{\nu}} \]

- **Womersley number**, \( \alpha \)

- **Amplitude of oscillations**, \( \varepsilon \)

- **Spherical domain**
Theoretical model I

Scalings

\[ u = \frac{u^*}{\omega_0 R_0}, \quad t = t^* \omega_0, \quad r = \frac{r^*}{R_0}, \quad p = \frac{p^*}{\mu \omega_0}, \]

where \( \omega_0 \) denotes the angular frequency of the domain oscillations, \( R_0 \) the sphere radius and \( \mu \) the dynamic viscosity of the fluid.

Dimensionless equations

\[ \alpha^2 \frac{\partial}{\partial t} u + \alpha^2 u \cdot \nabla u + \nabla p - \nabla^2 u = 0, \quad \nabla \cdot u = 0, \quad (r = 1), \]

\[ u = v = 0, \quad w = \varepsilon \sin \vartheta \sin t \]

(1)

where \( \varepsilon \) is the amplitude of oscillations. We assume \( \varepsilon \ll 1 \).

Asymptotic expansion

\[ u = \varepsilon u_1 + \varepsilon^2 u_2 + O(\varepsilon^3), \quad p = \varepsilon p_1 + \varepsilon^2 p_2 + O(\varepsilon^3). \]

Since the equations and boundary conditions for \( u_1, v_1 \) and \( p_1 \) are homogeneous the solution is \( p_1 = u_1 = v_1 = 0 \).
Theoretical model II

Velocity profiles on the plane orthogonal to the axis of rotation at different times.

- Limit of small $\alpha$: rigid body rotation;
- Limit of large $\alpha$: formation of an oscillatory boundary layer at the wall.
Experimental apparatus 1

The experimental apparatus is located at the University of Genoa.

- Perspex cylindrical container.
- Spherical cavity with radius $R_0 = 40$ mm.
- Glycerol (highly viscous Newtonian fluid).

(b) sin-16
The case of a viscoelastic fluid I

- As we deal with a sinusoidally oscillating linear flow we can obtain the solution for the motion of a viscoelastic fluid simply by replacing the real viscosity with a complex viscosity.

- In terms of our dimensionless solution this implies introducing a complex Womersley number.

- Rheological properties of the vitreous (complex viscosity) can be obtained from the works of ?, ?, and ?.

- It can be proved that in this case, due to the presence of an elastic component of vitreous behaviour, the system admits natural frequencies that can be excited resonantly by eye rotations.
Motion of a viscoelastic fluid in a sphere

Formulation of the problem I

The motion of the fluid is governed by the momentum equation and the continuity equation:

\[
\frac{\partial \mathbf{u}}{\partial t} + (\mathbf{u} \cdot \nabla)\mathbf{u} + \frac{1}{\rho} \nabla p - \frac{1}{\rho} \nabla \cdot \mathbf{d} = 0, \tag{3a}
\]

\[
\nabla \cdot \mathbf{u} = 0, \tag{3b}
\]

where \( \mathbf{d} \) is the deviatoric part of the stress tensor.

**Assumptions**

- We assume that the velocity is small so that nonlinear terms in (3a) are negligible.
- For a linear viscoelastic fluid we can write

\[
\mathbf{d}(t) = 2 \int_{-\infty}^{t} G(t - \tilde{t}) \mathbf{D}(\tilde{t}) d\tilde{t} \tag{4}
\]

where \( \mathbf{D} \) is the rate of deformation tensor and \( G \) is the relaxation modulus.

Therefore we need to solve the following problem

\[
\rho \frac{\partial \mathbf{u}}{\partial t} + \nabla p - \int_{-\infty}^{t} G(t - \tilde{t}) \nabla^2 \mathbf{u} \ d\tilde{t} = 0, \tag{5a}
\]

\[
\nabla \cdot \mathbf{u} = 0, \tag{5b}
\]
Relaxation behaviour I

We assume that the solution has the structure

$$u(x, t) = u_{\lambda}(x)e^{\lambda t} + c.c., \quad p(x, t) = p_{\lambda}(x)e^{\lambda t} + c.c.,$$

where $u_{\lambda}, p_{\lambda}$ do not depend on time and $\lambda \in \mathbb{C}$.

It can be shown that the deviatoric part of the stress tensor takes the form

$$d(t) = 2 \int_{-\infty}^{t} G(t - \tilde{t})D(\tilde{t})d\tilde{t} = 2D \tilde{G}(\lambda) \frac{\lambda}{\lambda},$$

(6)

where

$$\tilde{G}(\lambda) = G'(\lambda) + iG''(\lambda) = \lambda \int_{0}^{\infty} G(s)e^{-\lambda s}ds$$

is the complex modulus.

- $G'$: storage modulus;
- $G''$: loss modulus;

This leads to the eigenvalue problem

$$\rho \lambda u_{\lambda} = -\nabla p_{\lambda} + \frac{\tilde{G}(\lambda)}{\lambda} \nabla^2 u_{\lambda}, \quad \nabla \cdot u_{\lambda} = 0,$$

(7)

which has to be solved imposing stationary no-slip conditions at the wall and regularity conditions at the origin.
This eigenvalue problem can be solved analytically by expanding the velocity in terms of vector spherical harmonics and the pressure in terms of scalar spherical harmonics (\( ? \)).

Spatial structure of the first two eigenfunctions.
In order to determine the eigenvalues it is necessary to specify the model for the vitreous humour viscoelastic behaviour.

**Two-parameter model**

- dashpot: ideal viscous element
- spring: ideal elastic element

\[ \tilde{G}(\lambda) = \mu_K + \lambda \eta_K. \]

**Four-parameter model**

\[ \tilde{G}(\lambda) = \frac{\lambda \eta_m \mu_m (\mu_K + \lambda \eta_K)}{(\mu_m + \lambda \eta_m) (\lambda \eta_m \mu_m / (\mu_m + \lambda \eta_m) + \mu_K + \lambda \eta_K)}. \]
Some conclusions

- For all existing measurements of the rheological properties of the vitreous we find the existence of natural frequencies of oscillation.
- Such frequencies, for the least decaying modes, are within the range of physiological eye rotations ($\omega = 10 - 30 \text{ rad/s}$).
- The two- and the four-parameter model lead to qualitatively different results:
  - Two-parameter model: only a finite number of modes have complex eigenvalues;
  - Four-parameter model: an infinite number of modes have complex eigenvalues.
- Natural frequencies could be resonantly excited by eye rotations.
The effect of the geometry I

Myopic Eyes
In comparison to emmetropic eyes, myopic eyes are
- larger in all directions;
- particularly so in the antero-posterior direction.

Myopic eyes bear higher risks of posterior vitreous detachment and vitreous degeneration \(\rightarrow\) increased the risk of rhegmatogeneous retinal detachment.

The shape of the eye ball has been related to the degree of myopia (measured in dioptres \(D\)) by \(?\), who approximated the vitreous chamber with an ellipsoid.

\[
\begin{align*}
\text{width} &= 11.4 - 0.04D, \\
\text{height} &= 11.18 - 0.09D, \\
\text{length} &= 10.04 - 0.16D.
\end{align*}
\]

(a) horizontal and (b) vertical cross sections of the domain for different degrees of myopia.
Formulation of the mathematical problem

Equation of the boundary

\[ R(\vartheta, \varphi) = R_0 (1 + \delta R_1(\vartheta, \varphi)), \]

where

- \( R_0 \) denotes the radius of the sphere with the same volume as the vitreous chamber;
- \( \delta \) is a **small parameter** \( \delta \ll 1 \);
- the maximum absolute value of \( R_1 \) is 1.

**Expansion**

We expand the velocity and pressure fields in terms of \( \delta \) as follows

\[ U = U_0 + \delta U_1 + O(\delta^2), \quad P = P_0 + \delta P_1 + O(\delta^2). \]

**Solution**

The solution at the order \( \delta \) can be found analytically expanding \( R_1, U_1 \) and \( P_1 \) in terms of spherical harmonics.
Myopic eyes I

Maximum stress on the retina as a function of the refractive error

Maximum (over time and space) of the (a) tangential and (b) normal stress on the retina as a function of the refractive error in dioptres. **Values are normalised with the corresponding stress in the emmetropic (0 D) eye.** The different curves correspond to different values of the rheological properties of the vitreous humour taken from the literature.
Flow visualisations on planes containing the axis of rotation.
Theoretical model I

Second order solution

\[ \mathbf{u} = \varepsilon \mathbf{u}_1 + \varepsilon^2 \mathbf{u}_2 + \mathcal{O}(\varepsilon^3), \quad p = \varepsilon p_1 + \varepsilon^2 p_2 + \mathcal{O}(\varepsilon^3). \]

We decompose the velocity \( \mathbf{u}_2 \) and the pressure \( p_2 \) into their time harmonics by setting

\[ \mathbf{u}_2 = \mathbf{u}_{20} + \left\{ \mathbf{u}_{22} e^{2it} + \text{c.c.} \right\}, \quad p_2 = p_{20} + \left\{ p_{22} e^{2it} + \text{c.c.} \right\}, \quad \mathbf{u}_1 \cdot \nabla \mathbf{u}_1 = F_0 + \left\{ F_{2e}^{2it} + \text{c.c.} \right\}, \]

where \( \mathbf{u}_{20}, \mathbf{u}_{22}, p_{20}, p_{22}, F_0 \) and \( F_2 \) are independent of time.

Governing equations for the steady component

\[ \nabla^2 \mathbf{u}_{20} - \nabla p_{20} = \alpha^2 F_0, \quad \nabla \cdot \mathbf{u}_{20} = 0, \quad \nabla \cdot \mathbf{u}_{20} = 0, \]

\[ u_{20} = v_{20} = w_{20} = 0 \quad (r = 1). \]
The steady streaming flow can be directly measured experimentally by cross-correlating images that are separated in time by a multiple of the frequency of oscillation. This procedure filters out from the measurements the oscillatory component of the flow.

Effect of the geometry on the steady streaming

Non-sphericity of the domain

- The antero-posterior axis is shorter than the others;
- the lens produces an anterior indentation.

What is the effect of the geometry on the steady streaming?
Perturbation of the steady streaming

Theoretical model I

\[ \beta = -\varepsilon \cos (\omega_0 t^*) \quad \varepsilon \ll 1. \]

Scaling

\[ u = \frac{u^*}{\omega_0 R_0}, \quad t = t^* \omega_0, \quad (r, R) = \left( \frac{r^*, R^*}{R_0} \right), \quad p = \frac{p^*}{\mu \omega_0}. \]

Dimensionless governing equations

\[ \alpha^2 \left( \frac{\partial}{\partial t} - \varepsilon \sin t \frac{\partial}{\partial \varphi} \right) u + \alpha^2 (u \cdot \nabla) u + \nabla p - \nabla^2 u = 0, \quad (9a) \]
\[ \nabla \cdot u = 0, \quad (9b) \]
\[ u = v = 0, \quad w = \varepsilon R \sin \vartheta \sin t \quad \text{[} r = R(\vartheta, \varphi) \text{]}, \quad (9c) \]

Shape of the domain

We write the function \( R(\vartheta, \varphi) \) describing the shape of the domain as

\[ R(\vartheta, \varphi) = 1 + \delta R_1(\vartheta, \varphi), \quad \delta \ll 1. \]
Perturbation of the steady streaming flow on the equatorial plane
Perturbation of the steady streaming

Experimental measurement of the steady streaming flow

\[ \alpha = 3.8 \]

Steady streaming flow on the equatorial plane.

Steady streaming flow on the equatorial plane.
Eye movements during reading: $\approx 0.16 \, \text{rad}, \approx 63 \, \text{s}^{-1}$ (?).

Kinematic viscosity of the vitreous: $\nu \approx 7 \times 10^{-4} \, \text{m}^2\text{s}^{-1}$ (?).

Eye radius: $R_0 = 0.012 \, \text{m}$.

Womersley number: $\alpha = 3.6$.

Streaming velocity: $U = \varepsilon^2 \delta \max(|u_{21}^{(0)}|) \approx 6 \times 10^{-5} \, \text{m} \, \text{s}^{-1}$.

Diffusion coefficient of fluorescein: $D \approx 6 \times 10^{-10} \, \text{m} \, \text{s}^{-1}$ (Kaiser and Maurice, 1964)

**Peclét number**: $Pe \approx 1200$.

*In this case advection is much more important than diffusion!*
